

GENERAL DESCRIPTION

The SGM61010B is a high efficiency synchronous Buck DC/DC converter with 1A output current capability and adjustable output voltage. The input supply voltage is in the range of 2.5V to 5.5V.

For SGM61010B, it operates with a quasi-fixed 1.5MHz pulse width modulation (PWM) mode over the whole load range to achieve the best transient performance and lowest output voltage ripple. The device shutdown current is 0.05 μ A (TYP).

The SGM61010B provides an adjustable output voltage by an external resistor divider. The device is capable for low dropout operation with 100% duty cycle. Additional features include an internal soft-start function to limit inrush current, over-current and thermal shutdown protections, an enable input (EN), and input under-voltage lockout (UVLO) protection.

The SGM61010B is available in a Green SOT-23-5 package.

FEATURES

- 2.5V to 5.5V Input Voltage Range
- Adjustable Output Voltage from 0.6V to V_{IN}
- Low $R_{DS(on)}$ for Internal Switches: 230m Ω /150m Ω
- Forced Pulse Width Modulation Mode
- 100% Duty Cycle for Low Dropout Operation
- 1.5MHz PWM Switching Frequency
- Internal Soft-Start Limits the Inrush Current
- Output Discharge Function
- Over-Current Protection
- Thermal Shutdown Protection
- Input Under-Voltage Lockout (UVLO) Protection
- -40 $^{\circ}$ C to +125 $^{\circ}$ C Operating Temperature Range
- Available in a Green SOT-23-5 Package

APPLICATIONS

Battery Powered Application
General Purpose POL Supply
Set-Top Box
Network Video Camera
Wireless Router
Hard Disk Driver

PACKAGE/ORDERING INFORMATION

MODEL	PACKAGE DESCRIPTION	SPECIFIED TEMPERATURE RANGE	ORDERING NUMBER	PACKAGE MARKING	PACKING OPTION
SGM61010B	SOT-23-5	-40°C to +125°C	SGM61010BXN5G/TR	23I XXXXX	Tape and Reel, 3000

MARKING INFORMATION

NOTE: XXXXX = Date Code, Trace Code and Vendor Code.

XXXXX

Green (RoHS & HSF): SG Micro Corp defines "Green" to mean Pb-Free (RoHS compatible) and free of halogen substances. If you have additional comments or questions, please contact your SGMICRO representative directly.

ABSOLUTE MAXIMUM RATINGS

Voltage Range ⁽¹⁾

VIN, EN..... -0.3V to 6V

SW (DC) -0.3V to VIN + 0.3V

SW (AC, less than 10ns) ⁽²⁾..... -2V to 9V

FB -0.3V to 5.5V

Package Thermal Resistance

SOT-23-5, θ_{JA} 159.2°C/WSOT-23-5, θ_{JB} 40°C/WSOT-23-5, θ_{JC} 77.7°C/W

Junction Temperature +150°C

Storage Temperature Range -65°C to +150°C

Lead Temperature (Soldering, 10s) +260°C

ESD Susceptibility ^{(3) (4)}

HBM..... ±1500V

CDM ±1000V

NOTES:

1. All voltage values are with respect to the ground terminal.
2. While switching.
3. For human body model (HBM), all pins comply with ANSI/ESDA/JEDEC JS-001 specifications.
4. For charged device model (CDM), all pins comply with ANSI/ESDA/JEDEC JS-002 specifications.

RECOMMENDED OPERATING CONDITIONS

Input Voltage Range, VIN..... 2.5V to 5.5V

Output Voltage Range, VOUT 0.6V to VIN

Output Current Range, IOUT 0A to 1A

Operating Ambient Temperature Range..... -40°C to +125°C

OVERSTRESS CAUTION

Stresses beyond those listed in Absolute Maximum Ratings may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect reliability. Functional operation of the device at any conditions beyond those indicated in the Recommended Operating Conditions section is not implied.

ESD SENSITIVITY CAUTION

This integrated circuit can be damaged if ESD protections are not considered carefully. SGMICRO recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage. ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because even small parametric changes could cause the device not to meet the published specifications.

DISCLAIMER

SG Micro Corp reserves the right to make any change in circuit design, or specifications without prior notice.

PIN CONFIGURATION

PIN DESCRIPTION

PIN	NAME	TYPE	FUNCTION
1	EN	DI	Active High Enable Input. Apply a logic low to shut down the device or pull EN up to VIN to enable it. Do not leave EN floating.
2	GND	P	Ground Pin.
3	SW	P	Switching Node Output Pin. Connect to the filter inductor.
4	VIN	P	Power Supply Input. Decouple VIN with at least 10 μ F ceramic capacitor, close to the device.
5	FB	AI	Feedback Input. Use a resistor divider to feedback the output voltage to this pin and set the output voltage.

NOTE: DI = digital input, AI = analog input, O = output, P = power.

ELECTRICAL CHARACTERISTICS

(V_{IN} = 2.5V to 5.5V, T_J = -40°C to +125°C, typical values are at V_{IN} = 5.0V and T_J = +25°C, unless otherwise noted.)

PARAMETER	SYMBOL	CONDITIONS		MIN	TYP	MAX	UNITS

FUNCTIONAL BLOCK DIAGRAM

Figure 2. Block Diagram

DETAILED DESCRIPTION

Overview

The SGM61010B is a high efficiency Buck switching regulator specifically optimized for handheld battery-powered applications. Utilizing the adaptive off-time PWM control strategy, it operates at a quasi-fixed 1.5MHz switching frequency over the whole load range. This enables the use of compact inductors and capacitors for space-constrained designs.

SGM61010B delivers superior transient performance and minimal output voltage ripple. The typical shutdown current of the device is 0.05μA.

Under-Voltage Lockout (UVLO)

Operating with insufficient supply voltage can cause device malfunction or failure. The UVLO protection shuts down the device if the input voltage is below the V_{UVLO} threshold. The V_{UVLO} hysteresis is 150mV. When the input voltage exceeds the rising UVLO threshold, the device restarts with a fresh soft startup sequence.

Device Enable and the Output Discharge FET

When the input voltage is valid, pulling the EN input to logic high to enable the device and pulling it low to shut it down. In the shutdown mode, the switches and all control circuits are turned off to reduce the device current to 0.05μA (TYP). During shutdown, an internal FET is turned on and connects the SW pin to the GND through the internal discharge resistor which is typically 48Ω for smooth discharge of the output. This discharge function is also activated when the shutdown is caused by under-voltage lockout (UVLO) and thermal shutdown.

Soft-Start and Pre-biased Output

A 700μs internal soft-start circuit is included to prevent input inrush current and voltage drops during startup. This circuit slowly ramps up the error amplifier reference voltage when the device starts up. Soft-start limits inrush current during output capacitor charging and ensures smooth voltage rise. It also prevents input voltage droop when powering from high-impedance sources like primary and rechargeable batteries.

The SGM61010B is also capable of starting with a pre-biased output capacitor when it is powering up or enabled. When the device is turning on, a bias on the output may exist due to the other sources connected to the load(s) such as multi-voltage ICs or simply because of residual charges on the output capacitors. For example, when a device with light load is disabled and re-enabled, the output may not drop during the off-period and the device must restart under pre-biased output condition. Without the pre-biased capability, the device may not be able to startup properly. The output ramp is automatically initiated with the bias voltage and ramps up to the nominal output value.

Pulse Width Modulation (PWM)

The SGM61010B operates in PWM across the all load range. For light load, the inductor current can be negative when the low-side switch is on. However, if the current reaches the low-side sink current limit (I_{LIM_LN}), the low-side switch will be forced off.

Low Dropout Operation (100% Duty Cycle)

When the input voltage gradually drops to the regulation output voltage, the SGM61010B can operate at 100% duty cycle and keep the high-side MOSFET continuously on for minimal input-to-output voltage difference. The low-side MOSFET is kept off. In this mode, the lowest input voltage for keeping the output regulated is determined by load current and the resistive drops from the input to the output as given in Equation 1:

$$V_{IN_MIN} = V_{OUT} + I_{OUT_MAX} \times (R_{DS(on)} + R_L) \quad (1)$$

where:

V_{IN_MIN} is minimum input voltage to maintain output voltage in regulation.

I_{OUT_MAX} is maximum output current.

$R_{DS(on)}$ is high-side MOSFET on-resistance.

R_L is inductor DC resistance (DCR).

DETAILED DESCRIPTION (continued)**Switch Current Limits and Short-Circuit Protection**

The SGM61010B implements current limitation by sensing the current of the high-side switch. At the beginning of each cycle, the high-side switch is turned on. If the converter is overloaded or a short occurs on the output, the inductor current sensed by the high-side switch exceeds the maximum current limit threshold. Under this condition, the high-side switch is turned off to avoid damage. The shortened on-time will result in a reduced output voltage.

Note that the measured peak current limit in the closed-loop and open-loop (I_{LIM_HS}) test conditions is slightly different, mainly due to the current comparator propagation delay.

Thermal Shutdown Protection

A thermal shutdown function is implemented to prevent damage caused by excessive heat and power dissipation. Once the junction temperature exceeds +160°C, the device is shut down. The device is released from shutdown automatically when the junction temperature decreases by 20°C.

APPLICATION INFORMATION

An application circuit schematic of the SGM61010B with adjustable output is provided in Figure 3.

Figure 3. SGM61010B Application Example with 1.8V/1.0A Output

Output Voltage Setting

A resistor divider network (R_1 and R_2 in Figure 3) can be used to set the device output voltage based on the Equation 2. Use a 49.9kΩ resistor for R_2 to compromise between the quiescent current and the bias error/noise immunity of the FB pin.

$$V_{OUT} = V_{FB} \times \left(1 + \frac{R_1}{R_2}\right) = 0.6V \times \left(1 + \frac{R_1}{R_2}\right) \quad (2)$$

When V_{IN} decreases to near V_{OUT} value, the switching frequency is decreased and the duty cycle is increased until it reaches 100%.

A feed-forward capacitor (C_2) can be placed in parallel with R_1 to improve the bandwidth and achieve faster transient response.

Output Capacitor Design

For the device, the output capacitance is generally designed to limit the output voltage ripple below the required level. C_{OUT} also reduces the voltage transients when fast load changes occur. The inductor ripple current that is absorbed by C_{OUT} is determined by L , V_{OUT} and V_{IN} . The output voltage ripple is determined by the interaction of inductor current ripple with the capacitor impedance including its capacitance (C_{OUT}), ESR and ESL values.

During a load transient, the output capacitor provides or absorbs the extra load current alone that results in a droop or quick rise in its voltage, until the loop can

respond, and the inductor average current reaches the new load level. The C_{OUT} capacitance determines the transient magnitude. Bias voltage may cause capacitance decreasing significantly if ceramic capacitors are used. The effective deviation of a ceramic capacitor can be as high as -50% to +20% of the nominal value.

Note that high ripple current in the capacitor ESR can cause high temperature due to power dissipation in the capacitor. High operating temperature shortens the capacitor lifetime. Therefore, the maximum allowed ripple current in the capacitor that depends on the ambient temperature must not be exceeded.

Low ESL capacitors can be chosen if ringing in the low megahertz region is seen. Limiting the trace lengths on the PCB or replacing large capacitors with several smaller parallel ones can also help.

To have small output ripple and stable regulation loop, use low-ESR X5R or X7R ceramic capacitors with high ripple current ratings.

The output ripple caused by limited C_{OUT} capacitance and its parasitic ESR can be calculated from Equation 3:

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_{SW} \times L} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times \left(R_{ESR} + \frac{1}{8 \times f_{SW} \times C_{OUT}}\right) \quad (3)$$

In this example, a 10µF_10V_X7T_0603 ceramic capacitor is used.

APPLICATION INFORMATION (continued)

Inductor Design and Selection

In most cases, a 1μH to 2.2μH inductor works well for the device. Typically, a lower value inductor has a smaller physical size but may result in higher loss due to higher switching frequency required (the lower DCR may compensate for that at heavy loads). For a required ripple (ΔI_L), the inductor can be chosen based on Equation 4:

$$L = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times \Delta I_L \times f_{SW}} \quad (4)$$

Typically, the ΔI_L is chosen around 10% to 30% of the maximum load current. For lower output voltage settings, it is recommended to use 1μH inductor to achieve good response and stability.

Inductor manufacturers usually provide thermal current rating (I_{RMS}) and saturation current rating (I_{SAT}). Choose the I_{SAT} above the $(I_{LOAD,MAX} + \Delta I_L/2) \times 1.2$ to avoid saturation.

The inductor DCR is also an important factor for efficiency and loss consideration. For better efficiency, SGMICRO suggests to choose the DCR of the inductor as small as possible. More generally, choosing the saturation current above high-side limit is enough.

Input Capacitor Design

The input capacitor provides the converter pulsating and high frequency input currents, and decouples them from the input line. The C_{IN} impedance at the switching frequency should be very low and less than the source impedance to filter the switching currents and prevent them from flowing in the input source. The input voltage ripple must be small for proper regulation and stability. The following Equation 5 can be used to calculate C_{IN} based on the required peak-to-peak input ripple (ΔV_{IN}).

$$C_{IN} = \frac{\frac{V_{OUT}}{V_{IN}} \times (1 - \frac{V_{OUT}}{V_{IN}})}{\frac{\Delta V_{IN}}{I_{LOAD}} \times f_{SW}} \quad (5)$$

The worst case, ripple occurs when the duty cycle is near to 50% ($V_{OUT}/V_{IN} \approx 0.5$). Use Equation 6 to calculate C_{IN} :

$$C_{IN(MIN)} = \frac{1}{(\frac{\Delta V_{IN}}{I_{LOAD}}) \times 4 \times f_{SW}} \quad (6)$$

Use at least a 10μF low-ESR X5R or X7R ceramic capacitor for C_{IN} . A 10μF capacitor works well for most applications but for better filtering, a larger capacitor can be used. Consider the capacitor rated RMS current for the design. The C_{IN} RMS current is given by Equation 7:

$$I_{RMS} = I_{LOAD} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times (1 - \frac{V_{OUT}}{V_{IN}})} \quad (7)$$

In worst case, $I_{RMS(MAX)}$ is equal to 1/2 of the load DC current:

$$I_{RMS(MAX)} = \frac{1}{2} \times I_{LOAD} \quad (8)$$

Note that using long test leads for powering the converter on a lab bench can cause stability issues such as excessive ringing in the output during load transients. It is due to the large inductance of such wires that along with the low-ESR ceramic input capacitors create a high-Q network. Moreover, it can cause errors in loop phase and gain measurements. It is not the case in normal applications with short PCB traces feeding the input. However, if in an application the input inductance cannot be reduced, a high-ESR tantalum or aluminum electrolytic capacitor must be used in parallel with the low-ESR ceramic capacitors to stabilize the system by added the damping to the high-Q network.

LAYOUT CONSIDERATIONS

Some important PCB layout design considerations for the SGM61010B are listed below:

- Place the low-ESR input/output capacitors and the inductor as close as possible to the device with short, wide and direct traces on the same layer.

- Connect the GND terminal of the input and output capacitors together and to the device GND pin and the GND power plane in one point.
- Keep the FB feedback traces away from noisy elements or traces such as the SW node.
- Use GND layers under the device, switching traces and inductor for better shielding.
